Why XLisp-Stat?

GitHub repo for this talk: https://github.com/jharner/UseR2019xstatR

XLisp-Stat is little used since R has become the dominant open-source statistical computing platform, but it has many interesting features. It is now easy to use a Dockerized environment containing both R and XLisp-Stat. The talk presents two approaches for integrating R and XLisp-Stat.

XLisp-Stat has the following desirable features:

- a rich environment for dynamic graphics;
- a simple api for building graphical interfaces;
- a flexible, intuitive object-oriented system
- strong support for symbolic AI programming and much more!

xstatR 000000 Discussi

Integrating R and XLisp-Stat

Two dockerized environment have been created for integrating R and XLisp-Stat.

- xstatR for embedding R into XLisp-Stat using R as a dynamic library
- RXLisp for embedding XLisp-Stat into R using XLisp-Stat as a dynamic library

xstatR was originally presented by Jim Harner with programming support by Jun Tan in the 2009 Directions in Statistical Computing (DSC) Workshop held in Copenhagen.

RXLisp was developed by Duncan Temple Lang in 2002.

Both projects laid dormant until Docker made it possible to use the best features of R and XLisp-Stat.

Discussio

xstatR: Linking via the R dynamic library

xstatR GitHub repo: https://github.com/jharner/xstatR

xstatR is designed for the user who wants the full XLisp-Stat environment with extensions for advanced dynamic graphics and a full R environment both accessible by a command-line interface with X11 support.

- Allows for a natural interface for software written in C
- Calls R directly
- Does not depend on other software, except for R
- Needs no setup or configuration
- Compile R with the -enable-R-shlib option
- Recompile xlispstat after upgrading R (if necessary)

RXLisp: Linking via the XLisp-Stat dynamic library

RXLisp GitHub repo: https://github.com/jharner/RXLisp

RXLisp is designed for an R user who wants access to the dynamic graphics of XLisp-Stat using the syntax of R.

Loads XLisp into R as an R package

00000

- Implements a subset of XLisp-Stat, e.g., callbacks not currently supported
- Allows an R interface to XLisp-Stat (with an optional XLisp) interface)
- Requires little knowledge of XLisp-Stat except the functions of interest

What is Docker?

Docker containers provides a platform for running xstatR and RXLisp.

The two principal Docker entities are:

Image: an executable package that includes everything needed to run an application

Container: a runtime instance of an image

The image contains the code, configuration files, environmental variables, libraries, and the runtime. A container is an image with state, i.e., a user process.

The xstatR and RXLisp images provide complete, immutable solutions for embedding R in XLisp-Stat or embedding XLisp-Stat in R, respectively.

Data mapping 000000 Main functions

xstatR 000000 Lisp

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Discussion 0

High Level Lisp/R API

- Developed in Lisp
- Communicates with the low-level C macros/functions
- Provides convenient functions based on the embedded R environment
- Hides the embedded R environment from the user
- Is customizable and extendible, e.g., the user can customize the mapping between an R object and a Lisp object

Data type mapping

- Data type mapping needs to be dealt with in bridging/interface software
- One-to-one mapping is the ideal situation
- Due to the rich data structures in Lisp and R and their flexibility, no such mapping exists

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Introduction	xstatR Architecture	Data mapping	Main functions	xstatR	RXLisp	Discus
00000		○●○○○○	000000	000000	000	0

A possible solution

- Convert simple data types, e.g., vectors of scalers.
- Returns a reference to R objects rather than converting complex data types
- Depends on the user to retrieve information from the R object references

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

• Used by R interface packages such as JRI and RServe

itR R

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Discussion

Problems of this method

- R objects need to be locked to avoid garbage collection
- User is responsible for releasing R objects
- Proper access methods to the object references are needed

- Use a generic structure to represent R objects
- Copy the data into this structure, ignoring unrecognized components
- Unlock the R object by default after all information is copied
- Assign R objects to variable names to retain them in memory, if persistence is needed

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

The generic structure representing R objects

- A list of length one or three
- The first element is the data part
- The second and third elements, for R objects with attributes, are the attribute names and the attribute values
- Attribute name list is a list of strings
- Attribute value list provides the corresponding values of the named attributes

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

• Data part is either an array of scalars/strings, etc., or (recursively) a list of generic structures

Current Implementation

- Many complicated structures are (currently) copied without special handling, e.g., 1m objects.
- This structure is not convenient for direct use.
- The generic structure is a good foundation for building highly flexible conversions to meet users' needs, e.g., as has been implemented for data frames.

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Discussion

Low-level C Functions

- (callR "*R* statement")
 Parse and evaluate an R statement. The evaluation result will be copied into a generic structure and returned to the user.
- (saveToR "rName", lispObj)
 Save the value of lispObj into the embedded R environment (the value has to be encoded into the generic structure).

xstatR Low-level Examples

```
(setf y-list (callR "rnorm(50)"))
(setf y (first y-list))
(histogram y)
(saveToR "y" y-list)
```

High-level functions: converting R objects

- A prototype, Rengine-proto, was built to ease the process of calling R.
- Rengine-proto directly supports the xstatR package, but can be used by any xlispstat package.
- The user can determine how to convert an R object based on its class name, dimension, etc.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

• Rengine-proto currently includes loading data from R, saving an xstatR dataset to an R data frame, etc.

List of major methods

- (send R :call "statement" &key asis)
 Parse and evaluate a R statement.
 asis is a boolean value indicating whether to bypass the conversion process or not
- (send R :save "rName" lispObj &key attr attrNames)
 Save a lisp object to R. Attributes and names can be attached

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

 (send R :save-dataset "rName" lispObj &key cols rows)
 Save a dataset or part of a dataset as data frame in R troduction 0000 atR Architecture

RXLisp 000 Discussion

The xstatR package

- A lisp package used for dynamic graphics, data modeling, and multivariate analysis
- Dataset objects are defined in terms of observation objects
- Virtual datasets are constructed to encapsulate derived variables from model or other statistical objects
- Observations are objects viewable in different graphs
- Point state, color, and symbol are properties of the observation
- Changes in an observation value or property is immediately updated in its linked views
- R acts as a computational engine using the Lisp/R bridge

xstatR RXL

Discussion

More about virtual datasets for models

- Models generate derived variables from the original model variables.
- The newly generated data often need to be combined with the original dataset, e.g., to plot residuals against a predictor.
- SAS/JMP add (optionally) derived variables from models to the same dataset and the user soon loses track of which derived variables go with which model.
- R generates (optionally) named model and summary objects and the user soon loses track of the underlying models/summaries.
- Virtual datasets combined with tree-based model visualizations provide a solution.

More about virtual datasets for models (cont.)

A virtual dataset is able to bind new data with the original dataset without changing it. For each model, the user will only see the new data generated by the model and the original dataset.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへで

The RXLisp package provides an interface for calling XLisp-Stat functions from within R.

RXLisp has relatively few functions. The most important are:

- .XLispInit which initializes the XLisp-Stat engine so that it can be used to process calls to XLisp functions;
 - .XLisp which provides an interface to calling XLisp-Stat functions from R, converting the arguments from R values to XLisp-Stat objects and converting the resulting value back to an R object;
- [[.XLispReference which provide a way to invoke methods and access slots in XLisp objects from within R.

RXLisp Examples

- > library(RXLisp)
- > .XLispInit()
- > .XLisp("+", 1, 2, 3)
- > .XLisp("mean", c(1, 2, 3))

```
Generate a sample of 10 values from a Poisson distribution with mean 3.5.
```

```
> .XLisp("poisson-rand", as.integer(10), 3.5)
```

```
Reference objects
> h <- .XLisp("histogram", rnorm(100))
> .Xlisp("send", h, ":close")
or for a more R-like way
> h[["title"]]
> h$close()
```

RXLisp Graphics Examples

- > library(RXLisp)
- > .XLispInit()

```
Dynamic graphics
> myData <- list(rnorm(20), rnorm(20), rnorm(20))
> .XLisp("scatterplot-matrix", myData,
":variable-labels", list("a", "b", "c"))
or for a more R-like way
> With (" the labels of the pair of the second se
```

> .XLisp("scatterplot-matrix", myData, "variable-labels"= list("a", "b", "c"))

> .XLisp("spin-plot", myData)

Currently working on...

- Virtual datasets combine the "variables" in a dataset with the "derived variables" from a model object;
- The dataset browser shows the virtual dataset by clicking on the statistical object view, e.g., a model view;
- Virtual datasets support linking, e.g., for model diagnostic plots;
- Virtual model datasets combined with a model tree recursively allow model comparisons;
